

TESS from 2019-2021

Dec 15 2015

Simulations Working Group

Luke Bouma

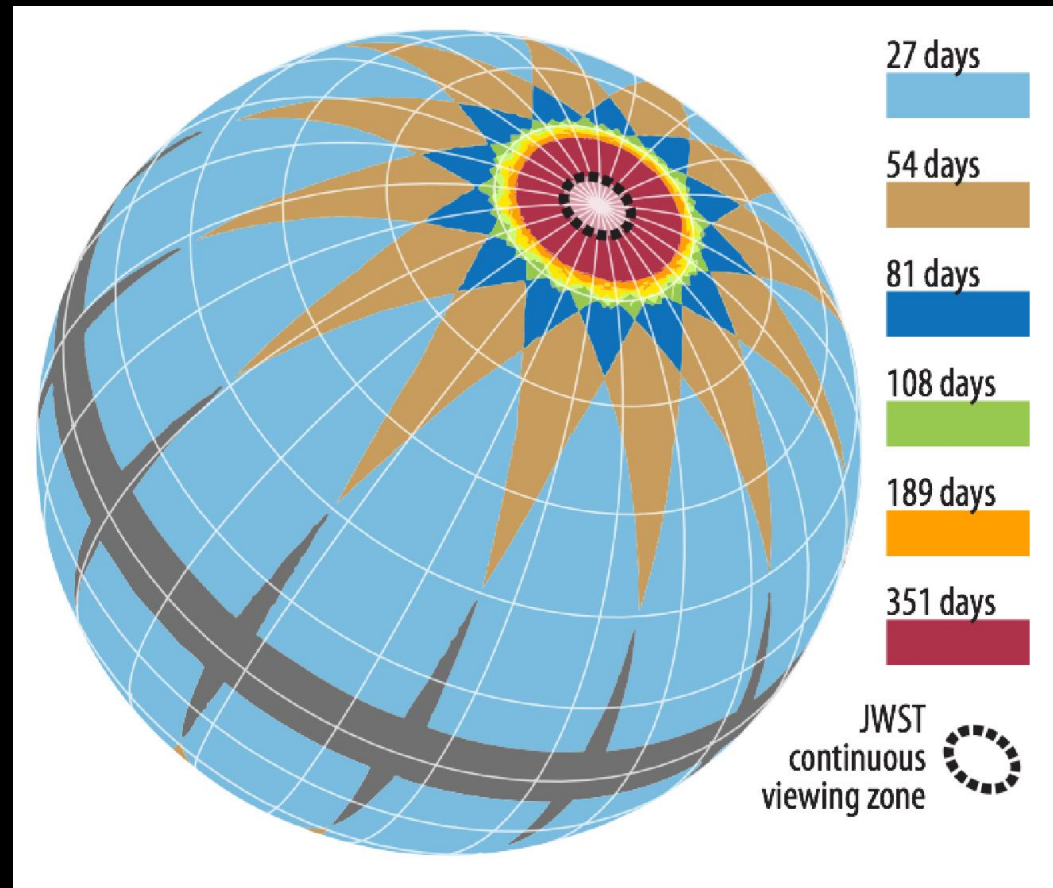

A) Which criteria should we use to compare observing plans after *TESS*'s first two years?

B) What specific observing plans should we evaluate?

Outline

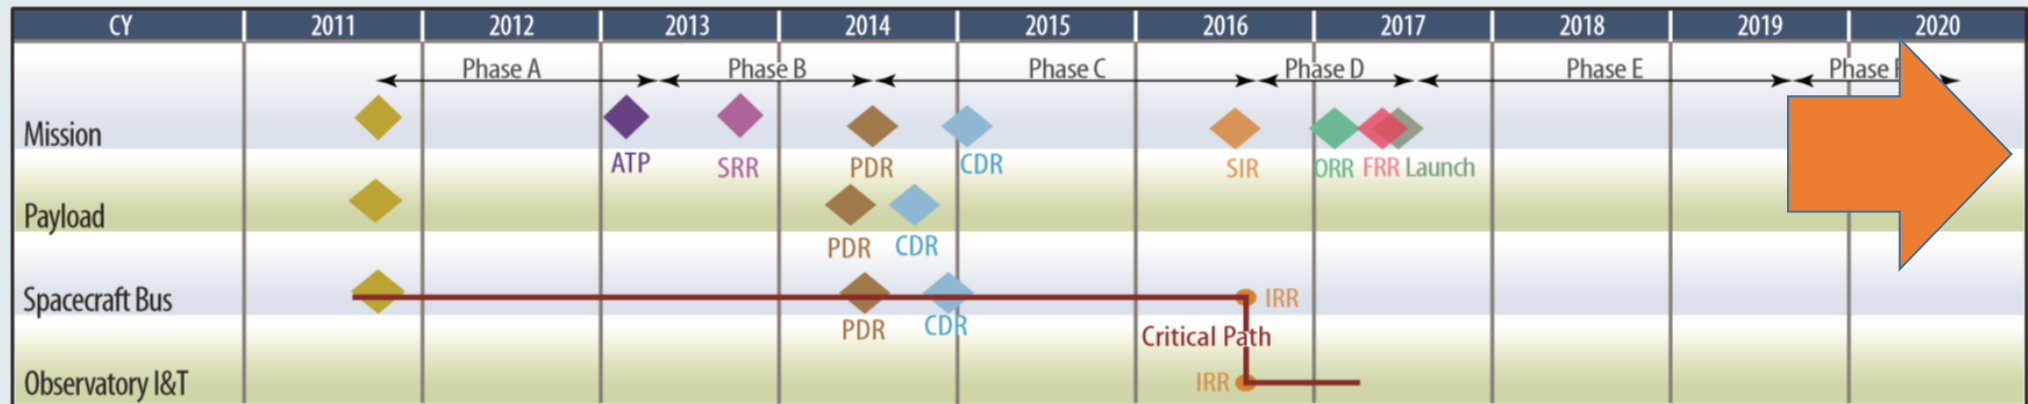

- Context within *TESS* mission timeline
- Yield calculation for planets and false positives
- Preliminary thoughts on:
 - Metrics for evaluation
 - Possible observing plans
- Discussion

Primary mission runs from late 2017-19;
target planets $R < 4R_E$ around bright stars

- There are no fundamental obstacles for 5-10 yrs
- Different observing strategies benefit different goals

SCHEDULE SUMMARY

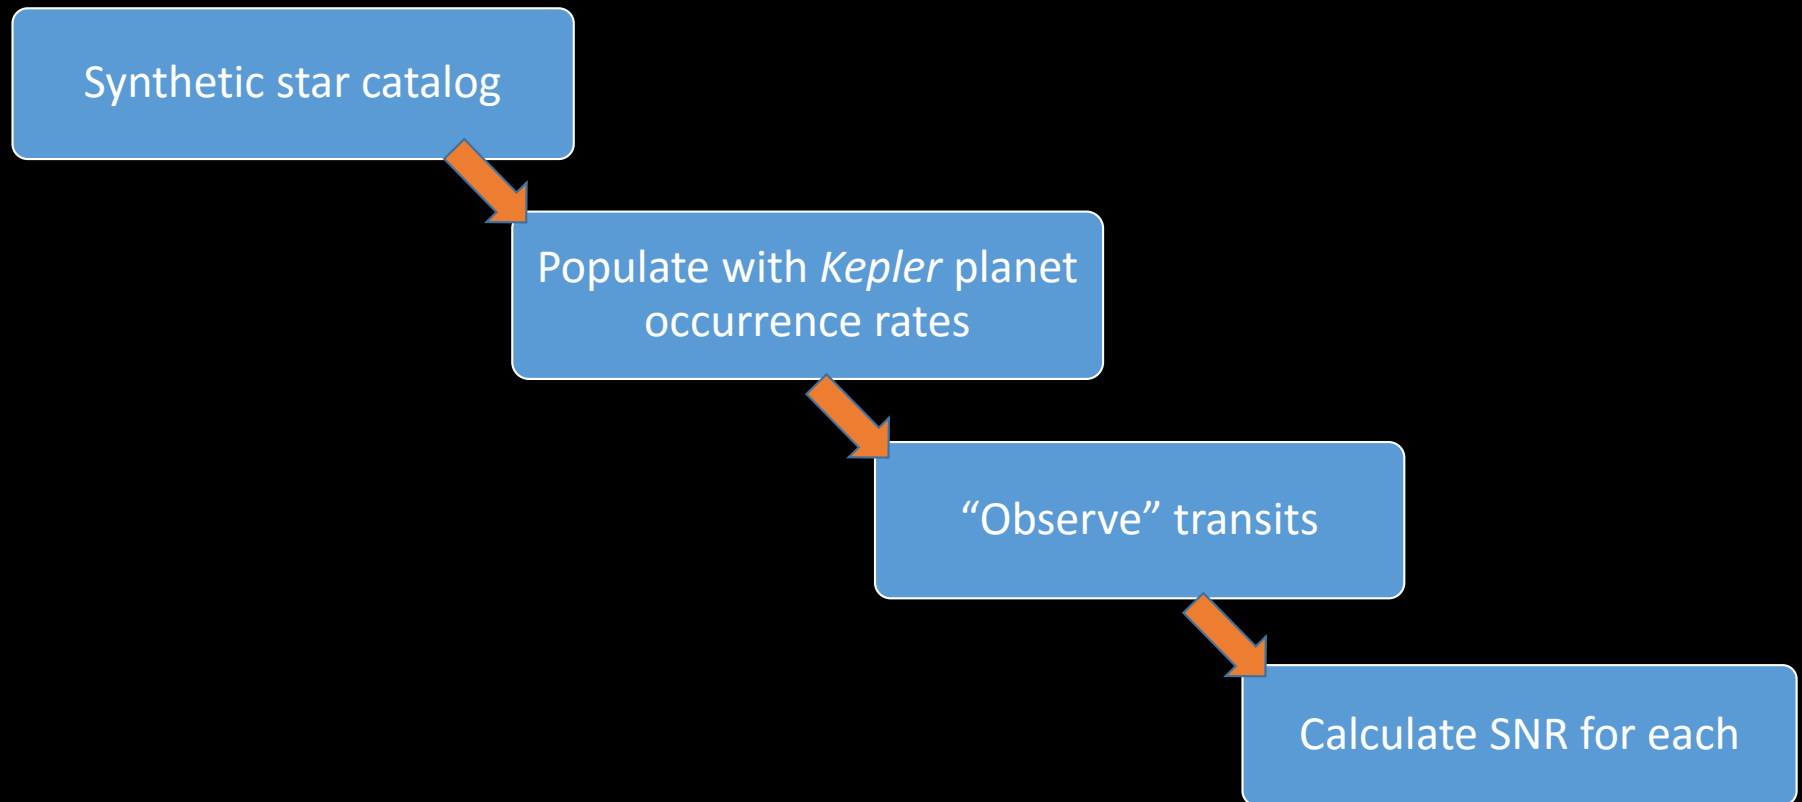

- There are no fundamental obstacles for 5-10 yrs
- Different observing strategies benefit different goals

SCHEDULE SUMMARY

Yield calculation overview

To ensure science goals are met, we monitor:

1. Detected planets
2. Host stars
3. Transits
4. Astrophysical false positives
5. “Marginal” detections

2019-21 figures of merit could focus towards new planets, new parameter spaces, or more details about known planets.

Hemisphere

NEP Focus

Ecliptic Focus

Microlensing:
single camera pointed at
galactic bulge; rest perform
photometry

Specific Scenarios

Primary survey repeat

- Advance phase to observe “gaps” (rocky planets about brightest stars)
- Enhance SNR and period sensitivity on known transiting planets
- Address ephemeris problem (*e.g.*, CoRoT)
- Experience from first run
- Short periods; ephemeris problem addressed by followup

- Advance phase to observe “gaps” (rocky planets about brightest stars)
- Enhance SNR and period sensitivity on known transiting planets
- Helps address “when does it transit” problem? (*e.g.*, CoRoT)
- Experience from first run
- (Can mitigate short period with longer dwell time)

Hemisphere

Single Field

- At an ecliptic pole, or at Kepler field, or at PLATO long-stare field
- Longest possible period coverage, of least # of targets
- Engineering constrained - need to keep solar panels towards sun

- Longer observing duration over medium number of targets.
 - Longer P , still cover $\sim 1/4$ of sky.
- Low # astrophysical false positives

NEP Focus

- Confirm *K2* targets (all campaigns, + uncovered fraction of sky from *K2* & *TESS* primary)
- Issues of zodiacal light as well as Earth and Moon transits

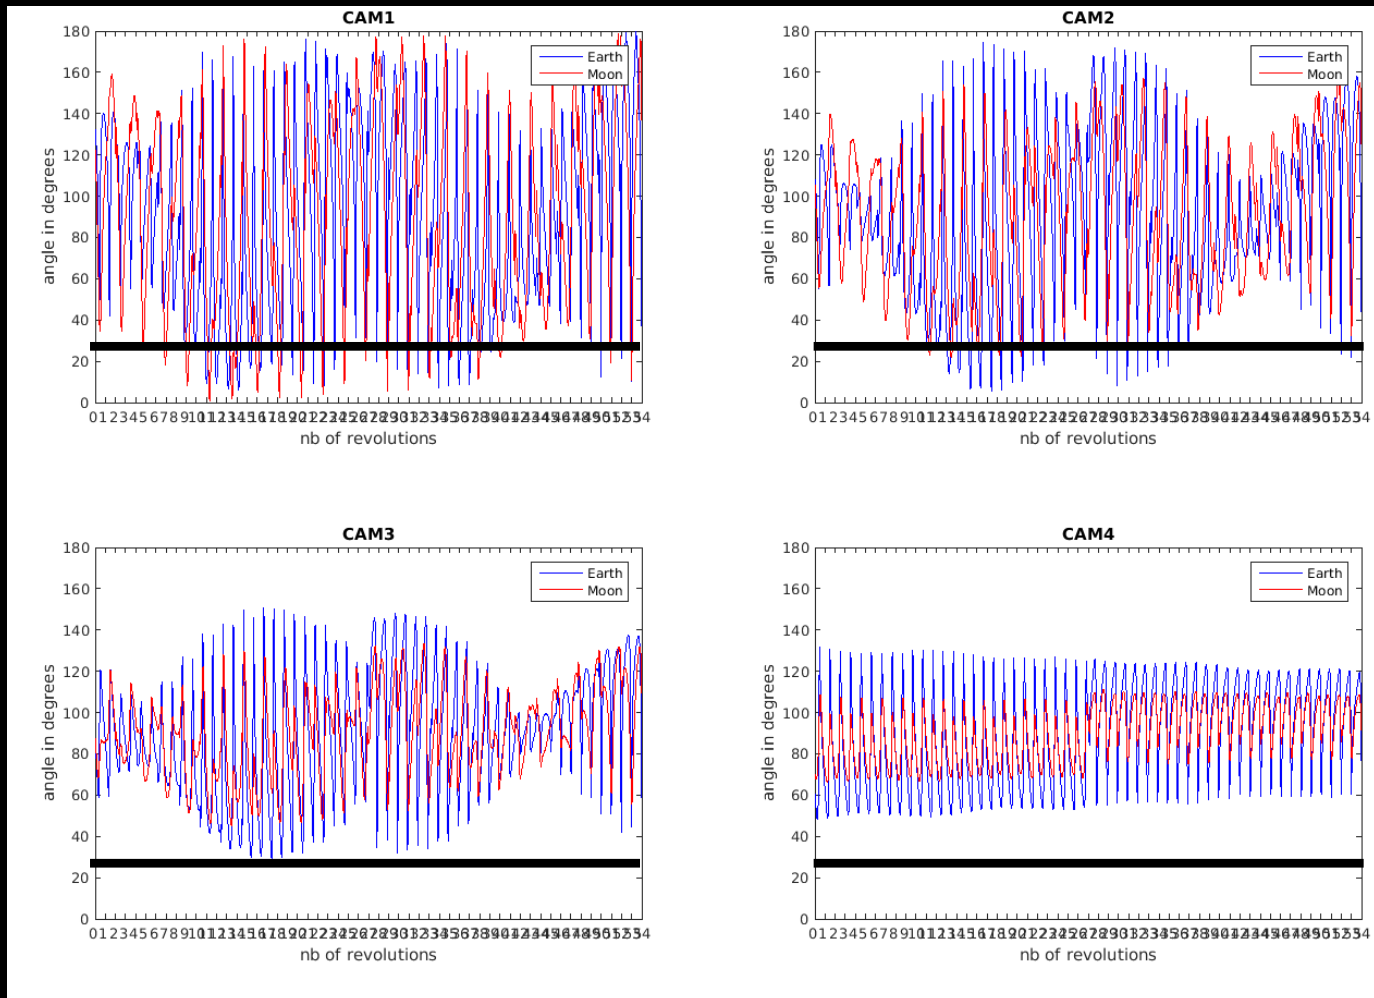

Ecliptic Focus

Issue with ecliptic: Earth and Moon transits

Primary mission already has a camera suffering from this

Ecliptic plane only: it gets worse
